states that the n th root of the volume of the Euclidean n -space is greater than or equal to the volumes of the individual sets. The effective variance of the sum of n independent densities in n -space is greater than the sum of the individual variances. Formally, the inequalities are interested in determining whether there is a fundamental idea

volume of A . If $A, B \subseteq \mathbf{R}^n$, A', B' are n -spheres such that

$f(x)dx$, where f is the probability density function of n -vectors with probabilities $H(X)$ and $H(Y)$, where X' and Y' are n -spheres such that $H(X') = H(X)$ and $H(Y') = H(Y)$.

1. Introduction

Suppose we start with a string of numbers (i.e., positive integers), say

5 5 5 5 5.

We might describe this in words in the usual way as "five fives," and write down the *derived string*

5 5.

This we describe as "two fives," so it yields the next derived string

2 5

which is "one two, one five," giving

1 2 1 5

namely, "one one, one two, one one, one five," or

1 1 1 2 1 1 1 5

and so on. What happens when an arbitrary string of positive integers is repeatedly derived like this?

I note that more usually one is given a sequence such as

55555 ; 55 ; 25 ; 1215 ; 11121115 ;

and asked to guess the generating rule or the next term.

The numbers in our strings are usually single-digit ones, so we'll call them *digits* and usually cram them together as we have just done. But occasionally we want to indicate the way the number in the string was obtained, and we can do this neatly by inserting commas recalling the commas and quotes in our verbal descriptions, thus:

5 5 5 5 5
 ,5 5,
 ,2 5,
 ,1 2,1 5,
 ,1 1,1 2,1 1,1 5,
 ...

The insertions of these commas into a string or portion thereof is called *parsing*.

We'll often denote repetitions by indices in the usual way, so that the derivation rule is

$$a^\alpha b^\beta c^\gamma d^\delta \dots \rightarrow \alpha a \beta b \gamma c \delta d \dots$$

When we do this, it is always to be understood that the repetitions are collected maximally, so that we must have

$$a \neq b, b \neq c, c \neq d, \dots$$

Since what we write down is often only a *chunk* of the entire string (i.e., a consecutive subsequence of its terms), we often use the square brackets "[" or "]" to indicate that the apparent left or right end really is the end. We also introduce the formal digits

0, as an index, to give an alternative way of indicating the ends (see below)

X for an arbitrary nonzero digit, and

$\neq n$ for any digit (maybe 0) other than n .

Thus $X^0 a^\alpha b^\beta c^\gamma$ means the same as $[a^\alpha b^\beta c^\gamma$
 $a^\alpha b^\beta c^\gamma X^0]$ means the same as $a^\alpha b^\beta c^\gamma]$
 $a^\alpha b^\beta c^\gamma X^{\neq 0}$ means $a^\alpha b^\beta c^\gamma$ followed by at least another digit,
 and $a^\alpha b^\beta c^{\gamma(\neq 2)^{\neq 0}}$ means that this digit is not a 2.

I'm afraid that this heap of conventions makes it quite hard to check the proofs, since they cover many more cases than one naively expects. To separate these cases would make this article very long and tedious, and the reader who really wants to check all the details is advised first to

spend some time practice

spend some time practicing the derivation process. Note that when we write $L \rightarrow L' \rightarrow L'' \rightarrow \dots$ we mean just that every string of type L derives to one of type L' , every string of type L' derives to one of type L'' , and so on. So when in our proof of the Ending Theorem we have

$$n^n] \xrightarrow{(n \neq 2)} n^{n^n} \rightarrow n']$$

the fact that the left arrow is asserted only when $n \neq 2$ does not excuse us from checking the right arrow for $n = 2$. (But, since $n > 1$ is enforced at that stage in the proof, we needn't check either of them for $n = 1$.)

By applying the derivation process n times to a string L , we obtain what we call its n th *descendant*, L_n . The string itself is counted among its descendants, as the 0th.

Sometimes a string factors as the product LR of two strings L and R whose descendants never interfere with each other, in the sense that $(LR)_n = L_n R_n$ for all n . In this case, we say the LR *splits* as $L.R$ (dots in strings will always have this meaning). It is plain that this happens just when (L or R is empty or) the last digit of L_n always differs from the first one of R_n . Can you find a simple criterion for this to happen? (When you give up, you'll find the answer in our Splitting Theorem.)

Obviously, we call a string with no nontrivial splittings an *atom*, or *element*. Then every string is the split product, or *compound*, of a certain number of elements, which we call the elements it *involves*. There are infinitely many distinct elements, but most of them only arise from specially chosen starting strings. However, there are some very interesting elements that are involved in the descendants of every string except the boring ones [] and [22]. Can you guess how many of these *common elements* there are? (Hint: we have given them the names Hydrogen, Helium, Lithium, ..., Uranium.)

It's also true (but ASTONISHINGLY hard to prove) that *every* string eventually decays into a compound of these elements, together with perhaps a few others (namely, isotopes of Plutonium and Neptunium, as

defined below). Moreover, all strings except the two boring ones increase in length exponentially at the same constant rate. (This rate is roughly 1.30357726903: it can be precisely defined as the largest root of a certain algebraic equation of degree 71.) Also, the relative abundances of the elements settle down to fixed numbers (zero for Neptunium and Plutonium). Thus, of every million atoms about 91790 on average will be of Hydrogen, the commonest element, while about 27 will be of Arsenic, the rarest one.

You should get to know the common elements, as enumerated in our Periodic Table. The abundance (in atoms per million) is given first, followed by the atomic number and symbol as in ordinary chemistry. The actual digit-string defining the element is the numerical part of the remainder of the entry, which, when read in full, gives the derivate of the element of next highest atomic number, split into atoms. Thus, for example, the last line of the Periodic Table tells us that Hydrogen (H) is our name for the digit-string 22, and that the next higher element, Helium (He), derives to the compound

Hf.Pa.H.Ca.Li

which we might call

"Hafnium-Protactinium-Hydrogen-Calcium-Lithide"!

Not everything is in the Periodic Table! For instance, the single digit string "1" isn't. But watch:

1
 11
 21
 1211
 111221
 312211
 13112221
 11132.13211 = Hf.Sn

after a few moves it has become Hafnium Stannide! This is an instance of our Cosmological Theorem, which asserts that the exotic elements (such as "1") all disappear soon after the Big Bang.

12211213322112

2. The Theory

We start with some easy theorems that restrict the possible strings after the first few moves. Any chunk of a string that has lasted at least n moves will be called an n -day-old string.

The One-Day Theorem. Chunks of types

$$,ax, bx, x^4 \text{ or more and } x^3 y^3$$

don't happen in day-old strings. (Note that the first one has a given parsing.)

Proof. The first possibility comes from $x^a x^b$, which, however, should have been written x^{a+b} , in the previous day's string. The other two, whichever way they are parsed, imply cases of the first.

The Two-Day Theorem. No digit 4 or more can be born on or after the second day. Also, a chunk 3×3 (in particular 3^3) can't appear in any 2-day-old list.

Proof. The first possibility comes from a chunk x^4 or more, while the second, which we now know must parse $,3x,3y$, can only come from a chunk $x^3 y^3$, of the previous day's string.

When tracking particular strings later, we'll use these facts without explicit mention.

The Starting Theorem. Let R be any chunk of a 2-day-old string, considered as a string in its own right. Then the starts of its descendants ultimately cycle in one of the ways

$$\begin{aligned} & [] \text{ or } [1^1 X^1 \rightarrow [1^3 \rightarrow [3^1 X^{\neq 3}]] \\ & \text{or } [2^2] \text{ or } [2^2 1^1 X^1 \rightarrow [2^2 1^3 \rightarrow [2^2 3^1 X^{\neq 3}]] \end{aligned}$$

If R is not already in such a cycle, at least three distinct digits appear as initial digits of its descendants.

Proof. If R is nonempty and doesn't start with 2^2 , then it *either* starts with a 1 and is of one of the types

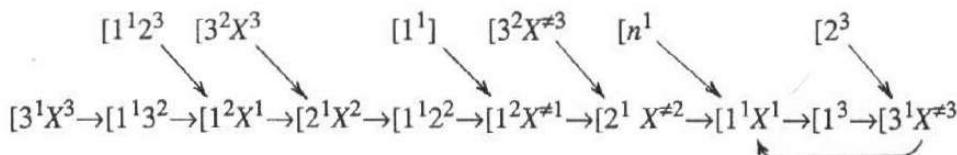

$$[1^1X^0 \text{ or } 1] \text{ or } [1^1(2^2 \text{ or } 3^2) \text{ or } 3^2] \text{ or } [1^2X^1 \text{ or } 1^1] \text{ or } [1^3]$$

or starts with a 2 and is of one of the types $[2^1X^2 \text{ or } 2^2] \text{ or } [2^3]$

or starts with a 3 and is of one of the types $[3^1X^3 \text{ or } 3^2] \text{ or } [3^2X^3 \text{ or } 3^1]$

or starts with some $n > 3$ and has form $[n^1]$.

It is therefore visible in

which establishes the desired results for it.

This proves the theorem except for strings of type $[2^2R'$ all of whose descendants start with 2^2 . This happens only if no descendant of R' starts with a 2, and so we can complete the proof by applying the results we've just found to R' .

The Splitting Theorem. A 2-day-old string LR splits as LR just if one of L and R is empty or L and R are of the types shown in one of

L	R
$n]$	$[m]$
$2]$	$[1^1X^1 \text{ or } 1^3 \text{ or } 3^1X^#3 \text{ or } [n^1]$
$\neq 2]$	$[2^21^1X^1 \text{ or } 2^21^3 \text{ or } 2^23^1X^#3 \text{ or } [2^2n^{(0 \text{ or } 1)}]$ $(n \geq 4, m \leq 3)$

Proof. This follows immediately from the Starting Theorem applied to R and the obvious fact that the last digit of L is constant.

R splits as $L.R$ just if one shown in one of

n^1
or $[2^2n^{(0 \text{ or } 1)}$

String Theorem applied to is constant.

Now we investigate the evolution of the end of the string!

The Ending Theorem. The end of a string ultimately cycles in one of the ways:

$$2.311322113212221] \rightarrow 2.13211322211312113211] \\ \uparrow \quad \downarrow \\ 2.12322211331222113112211] \leftarrow 2.111312211332211311221131221]$$

$$2.312221132221222112112322211n] \\ \uparrow \quad \downarrow \quad (n > 1) \\ 2.1311222113321132211221121332211n] \\ \text{or} \quad \curvearrowleft 2^2]$$

(Note: our splitting theorem shows that these strings actually do split at the dots, although we don't use this.)

Proof. A string with last digit 1 must end in one of the ways visible in

$$1^{\geq 3}] \rightarrow (\neq 2)^X 1^1] \rightarrow (\neq 2)^X 1^2] \rightarrow 2^{X \neq 2} 1^1] \rightarrow \\ 2^{X \neq 2} 1^2] \rightarrow 2^2 1^1] \rightarrow 2^2 1^2] \rightarrow 2^3 1^1]$$

and its subsequent evolution is followed on the right-hand side of Figure 1.

A string with last digit $n > 1$ must end $n^n]$ or $n^{\neq n}]$ and so evolves via

$$(n = 2) \quad \curvearrowleft n^n] \xrightarrow{(n \neq 2)} n^{\neq n}] \rightarrow n^1] \rightarrow 1n] \rightarrow 11n] \rightarrow (\neq 1)11n] \rightarrow 211n] \rightarrow 2211n]$$

and the last string here is the first or second on the left of Figure 1.

Figure 1. The evolution of endings other than 2^2].

This figure proves the theorem except for the trivial case 2^2]. (When any of these strings contains a dot, its subsequent development is only followed from the digit just prior to the rightmost dot.)

We are now ready for our first major result.

The Chemical Theorem.

- The descendants of any of the 92 elements in our Periodic Table are compounds of those elements.
- All sufficiently late descendants of any of these elements other than Hydrogen involve all 92 elements simultaneously.
- The descendants of any string other than [] or [22] also ultimately involve all 92 elements simultaneously.
- These 92 elements are precisely the common elements as defined in the introduction.

Proof.

- (a) follows instantly from the Periodic Table.
- (b) It also follows that if some time t , then the table will appear at the

E_n at $t \rightarrow Hf \delta$

$Hf \& Li$ at $t \rightarrow Hf \delta$

Hf at $t \rightarrow Sr \&$

U at $t \rightarrow E_n$

From these we
ments other than Hydrogen
Lithium will simultaneously
 $\leq t_0 + 100$, and the
Uranium at all times
elements at all times

In other words
appearing some of the
the time, and ultimately
time!

- (c) If L is not of form L'
Calcium (digit-string
both the bottom line
 L' , which does not exist)
- (d) follows from (a), (b)

Now we'll call an atom
common atoms.

Proof.

(a) follows instantly from the form in which we have presented the Periodic Table.

(b) It also follows that if the element E_n of atomic number n appears at some time t , then for any $m < n$, all elements on the E_m line of the table will appear at the later time $t + n - m$. In particular,

$$E_n \text{ at } t \rightarrow \text{Hf \& Li at } t + n - 1 \text{ (if } n \geq 2\text{)} ,$$

$$\text{Hf \& Li at } t \rightarrow \text{Hf \& Li at } t + 2 \text{ and } t + 71 ,$$

$$\text{Hf at } t \rightarrow \text{Sr \& U at } t + 72 - 38 ,$$

$$\text{U at } t \rightarrow E_n \text{ at } t + 92 - n .$$

From these we successively deduce that if any of these 92 elements other than Hydrogen is involved at some time t_0 , Hafnium and Lithium will simultaneously be involved at some strictly later time $\leq t_0 + 100$, and then both will exist at all times $\geq t_0 + 200$, Uranium at all times $\geq t_0 + 300$, and every other one of these 92 elements at all times $\geq t_0 + 400$.

In other words, once you can fool some of the elements into appearing some of the time, then soon you'll fool some of them all of the time, and ultimately you'll be fooling all of the elements all of the time!

- (c) If L is not of form $L'2^2$, this now follows from the observation that Calcium (digit-string 12) is a descendant of L , since it appears in both the bottom lines of Figure 1. Otherwise we can replace L by L' , which does not end in a 2.
- (d) follows from (a), (b), (c) and the definition of the common elements.

Now we'll call an arbitrary string *common* just if it is a compound of common atoms.

The Arithmetical Theorem.

- (a) The lengths of all common strings other than boring old [] and [22] increase exponentially at the same rate $\lambda > 1$.
- (b) The relative abundances of the elements in such strings tend to certain fixed values, all strictly positive.

Notes. Since each common element has at least 1 and at most 42 digits we can afford to measure the lengths by either digits or atoms: we prefer to use atoms. The numerical value of λ is 1.30357726903; the abundances are tabulated in the Periodic Table.

Proof. Let v be the 92-component vector whose (i) -entry is the number of atoms of atomic number i in some such string. Then at each derivation step, v is multiplied by the matrix M whose (i, j) -entry is the number of times E_j is involved in the derivate of E_i . Now our Chemical Theorem shows that some power of M has strictly positive (i, j) -entries for all $i \neq 1$ (the $(1, j)$ -entry will be 0 for $j \neq 1$, 1 for $j = 1$, since every descendant of a single atom of Hydrogen is another such).

Let λ be an eigenvalue of M with the largest possible modulus, and v_0 a corresponding eigenvector. Then the nonzero entries of $v_0 M^n$ are proportional to λ^n , while the entries in the successive images of all other vectors grow at most this rate. Since the 92 coordinate vectors (which we'll call H, He, \dots, U in the obvious way) span the space, at least one of them must increase at rate λ .

On the other hand, our Chemical Theorem shows that the descendants of each of He, Li, \dots, U increase as fast as any of them, and that this is at some rate > 1 , while H is a fixed vector (rate 1). These remarks establish our Theorem.

(We have essentially proved the Frobenius-Perron Theorem, that the dominant eigenvalue of a matrix with positive entries is positive and occurs just once, but I didn't want to frighten you with those long names.)

The Transuranic Elements

For each number $n \geq 1$ there is a string of length n consisting of an isotope of *Plutonium* followed by an isotope of *Neptunium*.

For $n = 2$, these would be Tu and Ne ; for $n = 3$, they would be Tu , Ne , and Pl ; and so on. They are called the transuranic elements, because they have atomic number n in our notation.

We can enlarge our notation to include new pairs of elements, called the transuranic elements.

Our proof of the Encyclopedic Theorem ultimately lands up as the Transuranic elements, and (see the decomposition)

Pu

Now $Pu \pm Np$ is a string of length n consisting of an isotope of *Plutonium* followed by an isotope of *Neptunium*, and so on. Because these strings are linear combinations of the transuranic elements, the relative abundances of the elements in the string are the same as in the original string.

So far, I can proudly claim that I have proved the Transuranic Theorem. However, I have not yet proved the Encyclopedic Theorem, which is the decomposition of the string $Pu \pm Np$ into its transuranic elements.

The Cosmological Theorem

Any string decays into shorter strings after a bounded number of steps. Every string other than the empty string has a finite lifetime, and the relative abundances of the elements in the string are the same as in the original string. The values we have already determined for the elements are consistent with this result.

The Transuranic Elements.

For each number $n \geq 4$, we define two particular atoms:

an isotope of *Plutonium* (Pu) : 31221132221222112112322211n

an isotope of *Neptunium* (Np): 1311222113321132211221121332211n

For $n = 2$, these would be Lithium (Li) and Helium (He); for $n = 3$, they would be Tungsten (W) and Tantalum (Ta), while for $n \geq 4$ they are called the transuranic elements. We won't bother to specify the number n in our notation.

We can enlarge our 92-dimensional vector space by adding any number of new pairs of coordinate vectors **Pu**, **Np** corresponding to pairs of transuranic elements.

Our proof of the Ending Theorem shows that every digit 4 or more ultimately lands up as the last digit in one of the appropriate pair of transuranic elements, and (see the bottom left of Figure 1) that we have the decomposition

$$Pu \rightarrow Np \rightarrow Hf.Pa.H.Ca.Pu.$$

Now $Pu \pm Np$ is an eigenvector of eigenvalue ± 1 modulo the subspace corresponding to the common elements, since $Pu \rightarrow Np$ modulo that space. Because these eigenvalues are strictly less than λ in modulus, the relative abundances of the transuranic elements tend to 0.

So far, I can proudly say that this magnificent theory is essentially all my own work. However, the next theorem, the finest achievement so far in Audioactive Chemistry, is the result of the combined labors of three brilliant investigators.

The Cosmological Theorem.

Any string decays into a compound of common and transuranic elements after a bounded number of derivation steps. As a consequence, every string other than the two boring ones increases at the magic rate λ , and the relative abundances of the atoms in its descendants approach the values we have already described.

Proof of the Cosmological Theorem would fill the rest of this book! Richard Parker and I found a proof over a period of about a month of very intensive work (or, rather, play!). We first produced a very subtle and complicated argument, which (almost) reduced the problem to tracking a few hundred cases, and then handled these on dozens of sheets of paper (now lost). Mike Guy found a simpler proof that used tracking and backtracking in roughly equal proportions. Guy's proof still filled lots of pages (almost all lost) but had the advantage that it found the longest-lived of the exotic elements, namely, the isotopes of *Methuselum* ($2233322211n$; see Figure 2). Can you find a proof in only a few pages? Please!

Figure 2. The descendants of Methuselum.

The Degree of λ .

Plainly, λ is an algebraic number, and we can reduce this bound to 71 by using the fact that the eigenvalues of M are the roots of the characteristic polynomial of M , which are the eigenvalues of M .

$$v_1 = H, v_2 = He - H$$

or, in atomic number notation,

$$v_1 = E_1, v_2 = E_2 - E_1$$

and also define

$$v_{21} = \{ Sc \}$$

then observe that

$$v_{21} \rightarrow v_{20} \rightarrow v_1$$

An alternate base for

of M with the respective eigenvalues

together with the following relations:

$$v_{21} - v_{19} \rightarrow v_1$$

(This shows that M is a diagonal matrix, and hence can be diagonalized. Don't be surprised if you don't understand more of linear algebra than you have!)

Richard Parker and I used the following degree equation for λ to prove the theorem. We used the fact that the number of eigenvalues of M is equal to the number of nonzero entries in M (since the nonzero ones satisfy $x^{q-1} = 1$).

Working always in the field of algebraic numbers, we can reduce the problem to finding the degree of the characteristic polynomial of M , which is the product of the degrees of the eigenvalues of M . This is the degree of the characteristic polynomial of M , which is the product of the degrees of the eigenvalues of M .

The Degree of λ .

Plainly, λ is an algebraic number of degree at most 92. We first reduce this bound to 71 by exhibiting a 21-dimensional invariant subspace on which the eigenvalues of \mathbf{M} are 0 or ± 1 .

$$\mathbf{v}_1 = \mathbf{H}, \mathbf{v}_2 = \mathbf{He} - \mathbf{Ta}, \mathbf{v}_3 = \mathbf{Li} - \mathbf{W}, \dots, \mathbf{v}_{20} = \mathbf{Ca} - \mathbf{Pa},$$

or, in atomic number notation,

$$\mathbf{v}_1 = \mathbf{E}_1, \mathbf{v}_2 = \mathbf{E}_2 - \mathbf{E}_{73}, \mathbf{v}_3 = \mathbf{E}_3 - \mathbf{E}_{74}, \dots, \mathbf{v}_{20} = \mathbf{E}_{20} - \mathbf{E}_{91},$$

and also define

$$\mathbf{v}_{21} = \{ \mathbf{Sc} + \mathbf{Sm} - \mathbf{H} - \mathbf{Ni} - \mathbf{Er} - 3\mathbf{U} \}/2,$$

then observe that

$$\mathbf{v}_{21} \rightarrow \mathbf{v}_{20} \rightarrow \mathbf{v}_{19} \rightarrow \dots \rightarrow \mathbf{v}_4 \rightarrow \mathbf{v}_3 \rightarrow \mathbf{v}_2, \mathbf{v}_1 \rightarrow \mathbf{v}_1.$$

An alternate base for this space consists of the eigenvectors

$$\mathbf{v}_1 \text{ and } \mathbf{v}_3 \pm \mathbf{v}_2$$

of \mathbf{M} with the respective eigenvalues

$$1 \text{ and } \pm 1,$$

together with the following Jordan block of size 18 for the eigenvalue 0

$$\mathbf{v}_{21} - \mathbf{v}_{19} \rightarrow \mathbf{v}_{20} - \mathbf{v}_{18} \rightarrow \mathbf{v}_5 - \mathbf{v}_3 \rightarrow \mathbf{v}_4 - \mathbf{v}_2 \rightarrow 0.$$

(This shows that \mathbf{M} is one of those "infinitely rare" matrices that cannot be diagonalized. Don't expect to follow these remarks unless you've understood more of linear algebra than I fear most of your colleagues have!)

Richard Parker and I have recently proved that the residual 71st degree equation for λ is irreducible, even when it is read modulo 5. We use the fact that the numbers in a finite field of order q all satisfy $x^q = x$ (since the nonzero ones form a group of order $q - 1$, and so satisfy $x^{q-1} = 1$).

Working always modulo 5, we used a computer to evaluate the sequence of matrices.

$$M_0 = M, M_1 = M_0^5, M_2 = M_1^5, M_3 = M_2^5, \dots, M_{73} = M_{72}^5,$$

and to verify that the nullity (modulo 5) of $M_{n+2} - M_2$ was 21 for $1 \leq n \leq 70$, but 92 for $n = 71$. Note that the 21 vectors of the above "alternate base" are *eigenvectors* of M_2 whose eigenvalues (modulo 5) lie in the field of order 5.

If the 71st degree equation were reducible modulo 5, then M_2 would have an eigenvector linearly independent of these with eigenvalue lying in some extension field of order $q = 5^n$ ($1 \leq n \leq 70$). But then the eigenvalues ϕ of these 22 eigenvectors would all satisfy $\phi^q = \phi$, and the 22 eigenvectors would be nullvectors for

$$(\mathbf{M}_2)^q - \mathbf{M}_2 = \mathbf{M}_{n+2} - \mathbf{M}_2,$$

contradicting our computer calculations.

It is rather nice that we were able to do this without being able to write down the polynomial. However, Professor Oliver Atkin of Chicago has since kindly calculated the polynomial explicitly and has also evaluated its largest root λ as

1.3035772690342963912570991121525498

approximately. The polynomial is

$$\begin{aligned}
& x^{71} - x^{69} - 2x^{68} - x^{67} + 2x^{66} + 2x^{65} + x^{64} - x^{63} - x^{62} - x^{61} \\
& - x^{60} - x^{59} + 2x^{58} + 5x^{57} + 3x^{56} - 2x^{55} - 10x^{54} - 3x^{53} - 2x^{52} + 6x^{51} \\
& + 6x^{50} + x^{49} + 9x^{48} - 3x^{47} - 7x^{46} - 8x^{45} - 8x^{44} + 10x^{43} + 6x^{42} + 8x^{41} \\
& - 5x^{40} - 12x^{39} + 7x^{38} - 7x^{37} + 7x^{36} \overset{+}{\cancel{}} x^{35} - 3x^{34} + 10x^{33} + x^{32} - 6x^{31} \\
& - 2x^{30} - 10x^{29} - 3x^{28} + 2x^{27} + 9x^{26} - 3x^{25} + 14x^{24} - 8x^{23} - 7x^{21} \\
& + 9x^{20} + 3x^{19} - 4x^{18} - 10x^{17} - 7x^{16} + 12x^{15} + 7x^{14} + 2x^{13} - 12x^{12} - 4x^{11} \\
& - 2x^{10} + 5x^9 + x^7 - 7x^6 + 7x^5 - 4x^4 + 12x^3 - 6x^2 + 3x - 6
\end{aligned}$$

SOLUTIONS

Here we have some problems the first day, solutions on the third day. Could their egos tied up in giving problems take more than a half hour to actually be solved at the conference by Gallager -- an interesting

Boyd and Hajela have considered Gambler's Ruin on the Sphere for three dimensions. They are very happy with the technique of selection problem of T. C. Tsoi under moment constraints. It is generally true, but at this time moment constraints can be removed.

So here we have it. be solved. It is conceivable this book as a source of will act as a clearing house book, so potential research problems.
